

The top of the slide features a background of binary code (0s and 1s) in a light green color. On the left side, there is a red rectangular box containing the CEA Tech logo. The logo consists of the text "FROM RESEARCH TO INDUSTRY" in small, white, uppercase letters at the top. Below this, the word "cea" is written in a white, lowercase, sans-serif font, followed by "tech" in a larger, white, lowercase, sans-serif font. A thin, horizontal green line is positioned below the word "cea".

FROM RESEARCH TO INDUSTRY

cea tech

Compilation for cyber-security in embedded systems

Workshop SERTIF

Damien Couroussé

CEA – LIST / LIALP; Grenoble Université Alpes

damien.courousse@cea.fr

The bottom of the slide features a decorative pattern of thin, light brown lines that resemble a complex circuit board or network diagram. The lines are interconnected and form a dense, grid-like structure across the width of the slide.

Typology of attacks

■ Cryptanalysis

Out of our scope

■ **Passive attacks.** side channel attacks

Observations: power, electro-magnetic, execution time, temperature, etc.

■ **Active attacks.** fault attacks

Over/under voltage, laser, ion beam, EM, clock glitches...

■ **Reverse engineering**

Hardware inspection: mechanical or chemical etching, scope observation...

Software inspection: debug, memory dumps, code analysis...

Using physical attacks: SCARE, FIRE...

■ **Logical attacks**

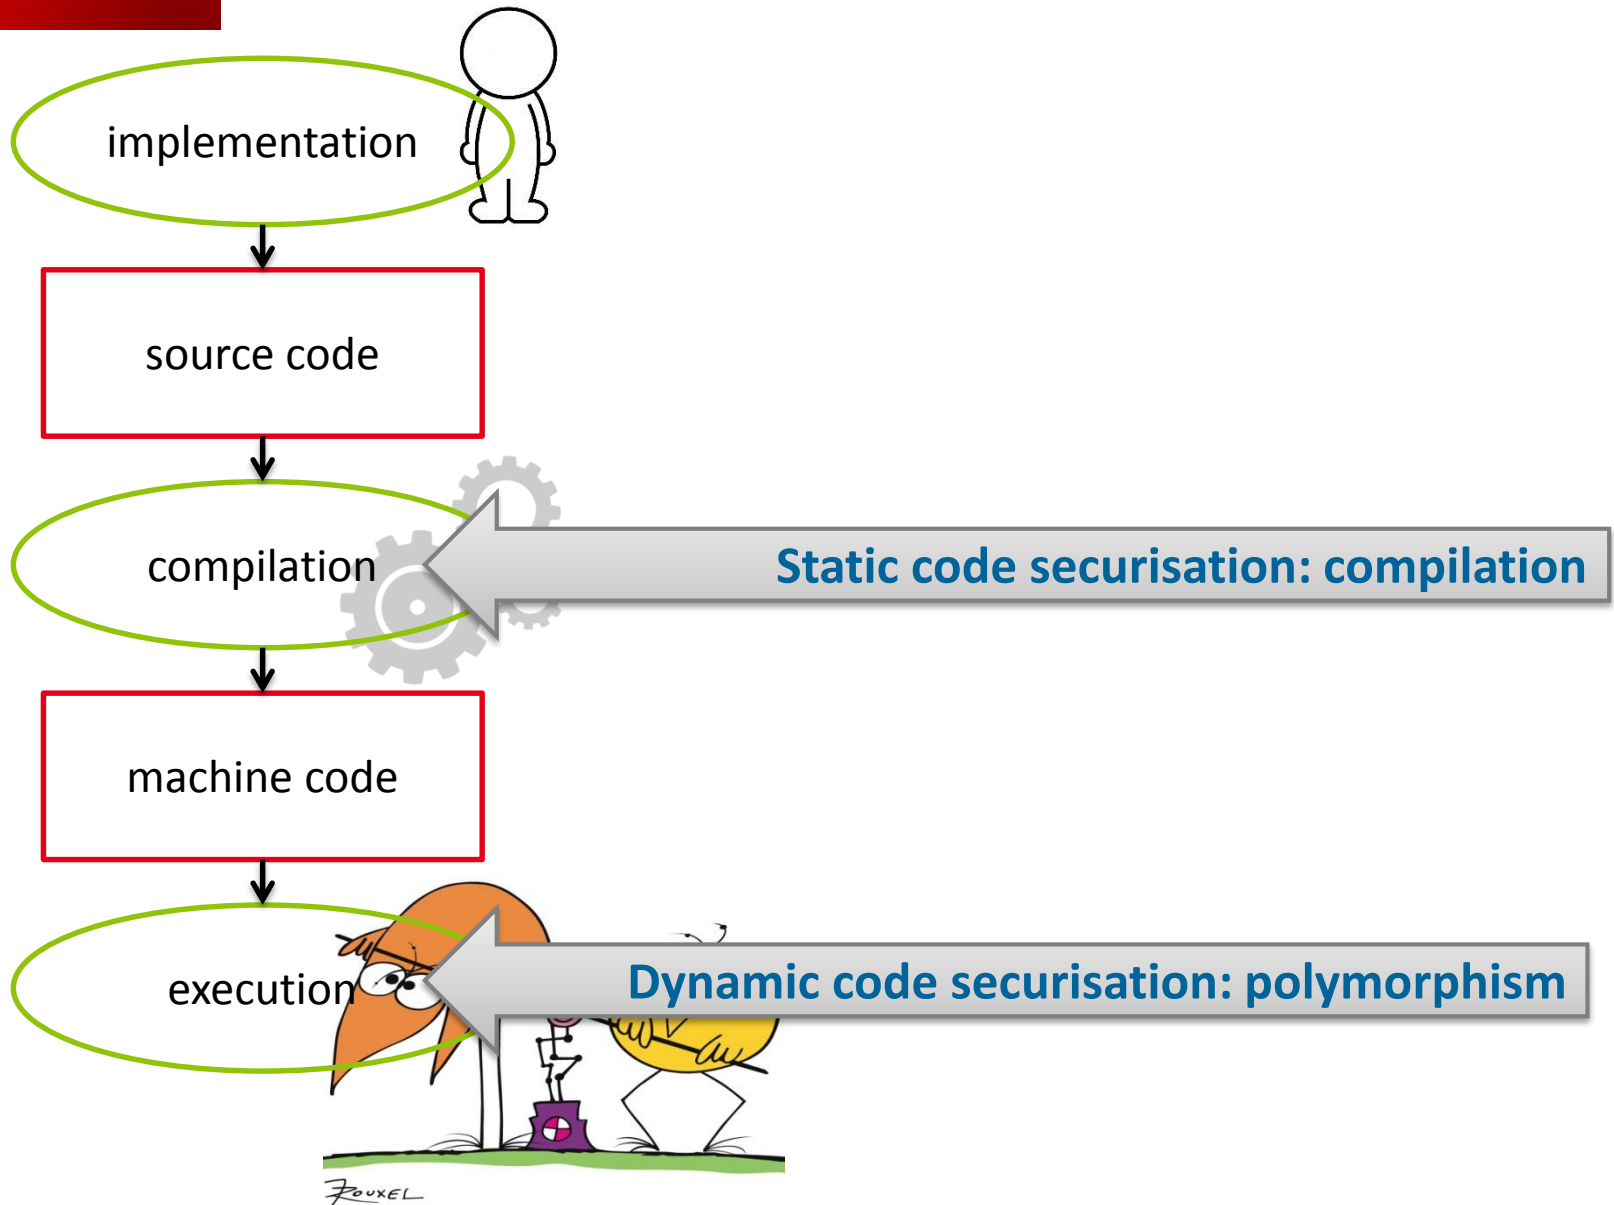

Not (yet) considered

Real world attacks are different from research literature

■ **First step.** Global analysis, calibration of the attack bench(es), identification of weaknesses

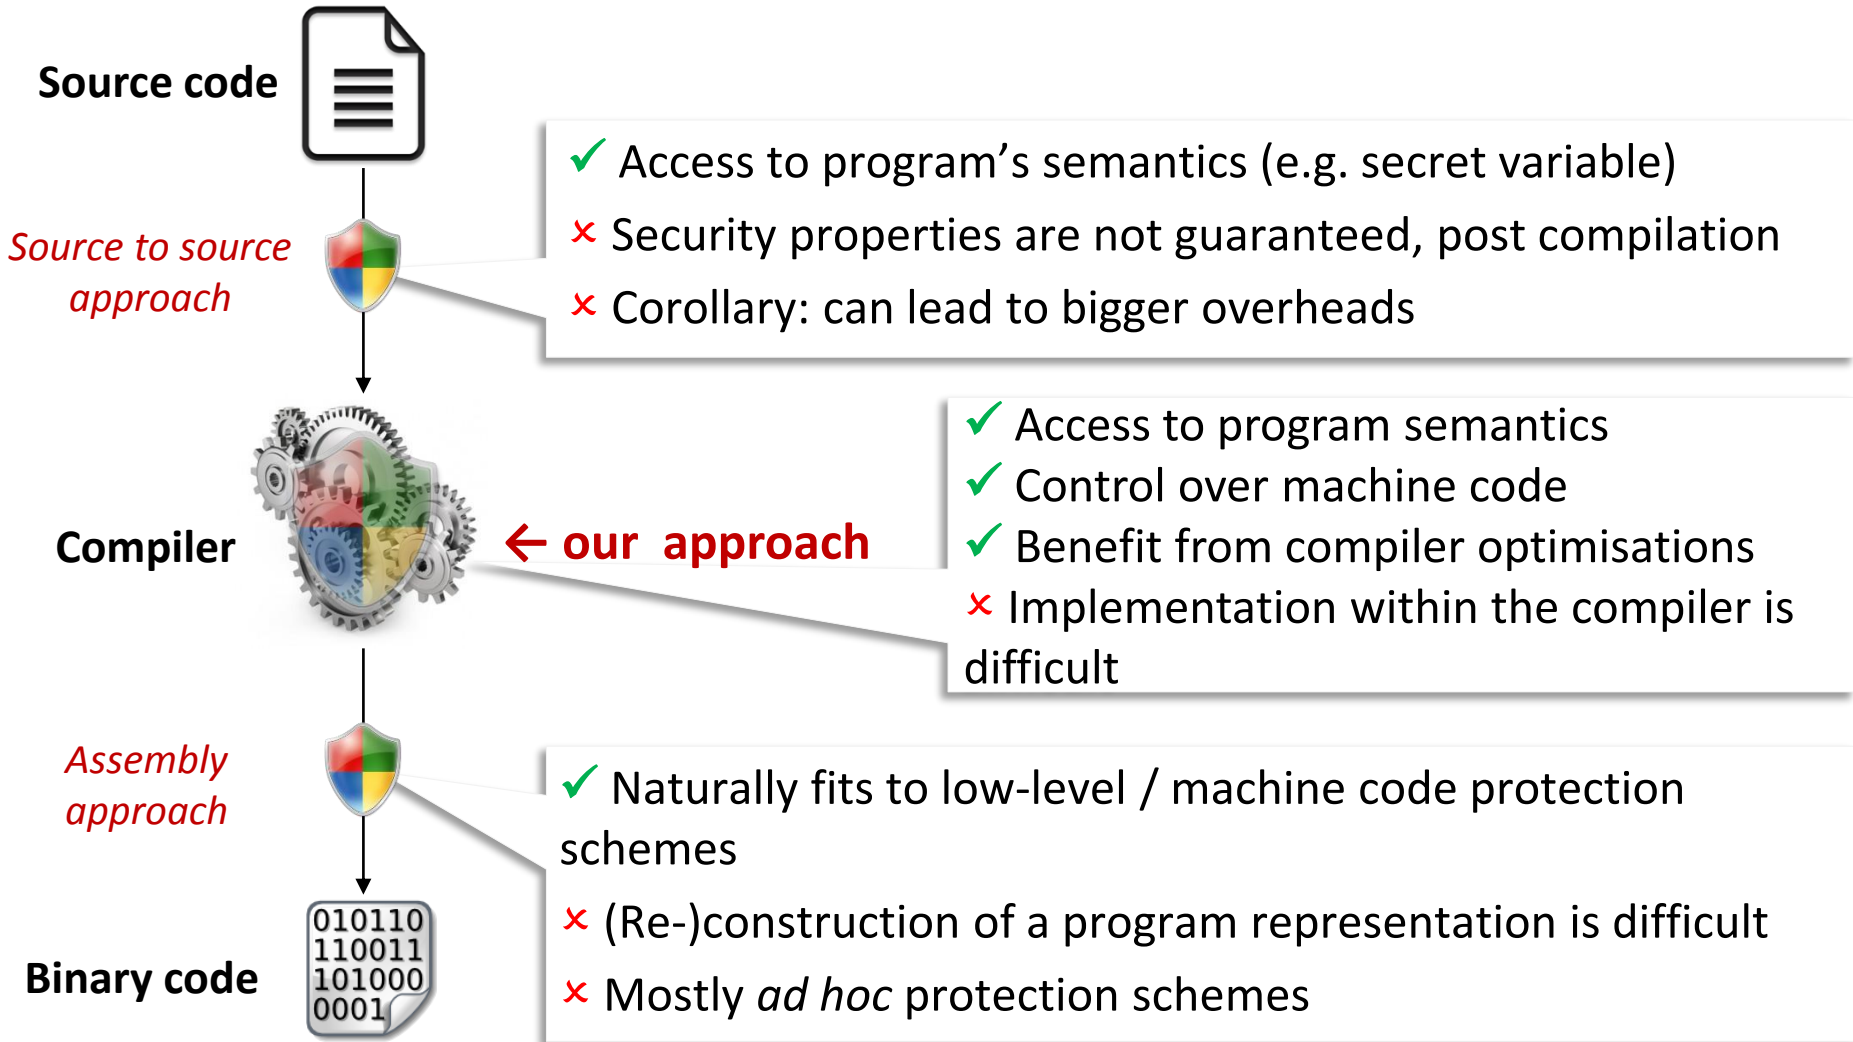

■ **Second step.** The textbook attack: a focused attack on a known weakness

FROM THE IDEA TO A PRODUCT: A DETAILED PLAN

**STATIC COMPILATION OF
PROTECTIONS
AGAINST FAULT ATTACKS**

AUTOMATED APPLICATION OF COUNTERMEASURES WITH STATIC COMPILATION

COMPILATION OF A COUNTERMEASURE AGAINST INSTRUCTION SKIP FAULT ATTACKS

- Attack model: faults, instruction skip
- Protection model: instruction redundancy
 - Formally verified countermeasure model [Moro et al., 2014]

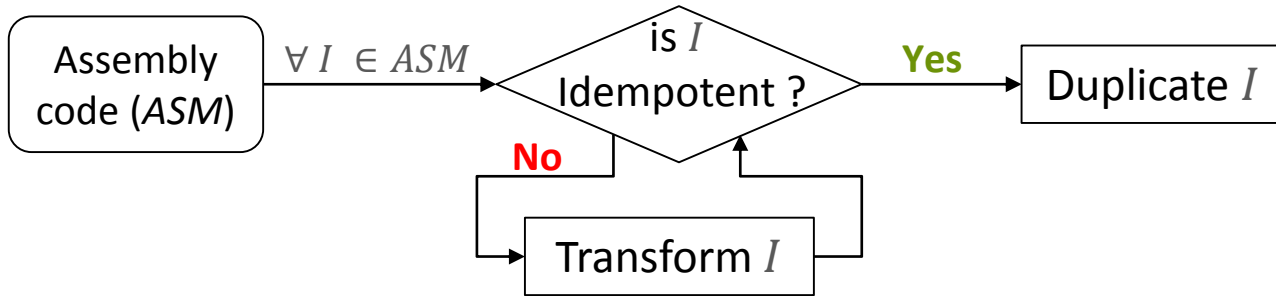

■ Platform

STM32 F100: ARM Cortex-M3
Frequency: 24 MHz
Instruction Set: Thumb2

■ Workflow

INSTRUCTION DUPLICATION SCHEME

"An instruction is idempotent when it can be re-executed several times with always the same result"

Example

is idempotent

```

add R0, R1, R2  →  Duplicaton  →  add R0, R1, R2
add R0, R1, R2
  
```

Is not idempotent

```

add R1, R1, R2  →  ✗  →  add R1, R1, R2
add R1, R1, R2
  
```

Transformation
[Moro et al. 2014]

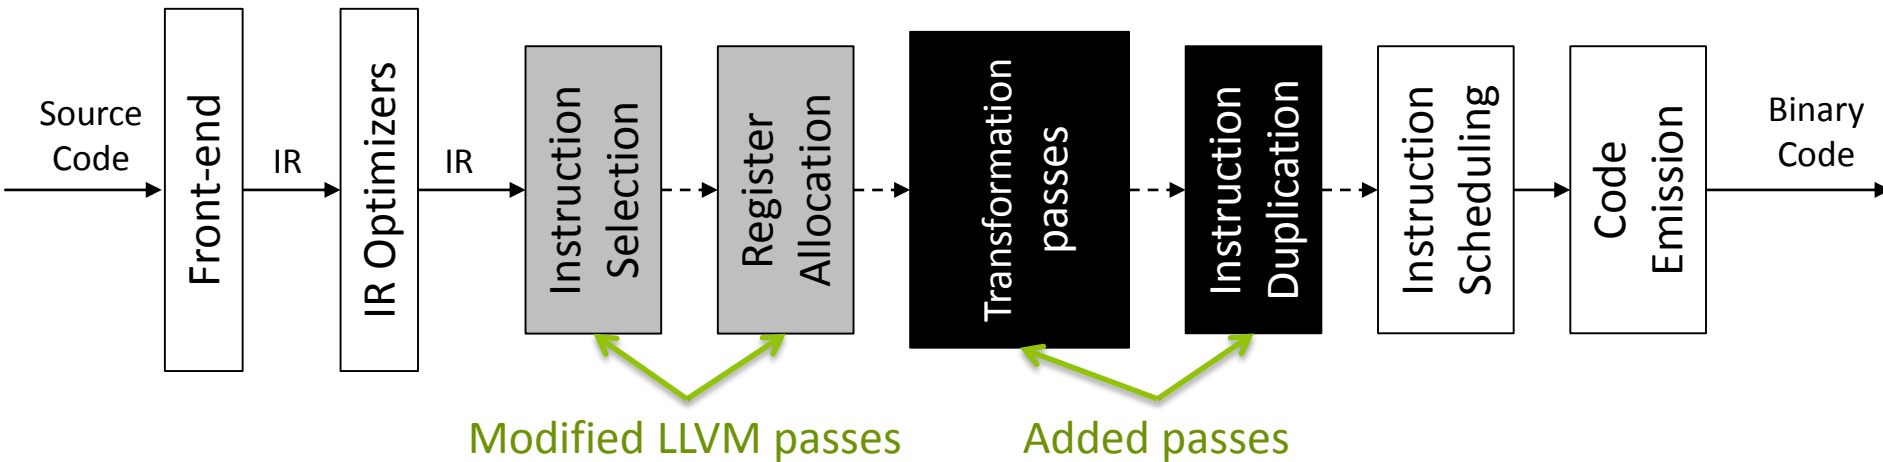

```

mv RX, R1
add R1, RX, R2  →  Duplicaton  →  mv RX, R1
mv RX, R1
add R1, RX, R2
add R1, RX, R2
  
```

Issues

- **How to find a free register at the assembly code level ?**
 - [Barengi et al. 2010]: ad hoc implementation. the number of free registers is known for their implemented AES
 - [Moro et al. 2014]: use of the scratch register `r12`
- **Overhead:**
 - At least $\times 4$ for each instruction
 - [Moro et al. 2014] Reported $\times 14$ for the ARM instruction: `umla1`

INSTRUCTION DUPLICATION WITH LLVM

■ Instruction selection

- Force three-operands instructions

■ Register allocation

- Force the use of different registers for source and destination operands

`add r0, r0, r1` => `add r2, r0, r1`

■ Transformation passes

- Transformation of non-idempotent instructions into a sequence of idempotent ones

■ Instruction duplication

- Straightforward. Could (should?) be executed *after* instruction scheduling

COMPILATION OF A COUNTERMEASURE AGAINST INSTRUCTION SKIP FAULT ATTACKS

- Attack model: faults, instruction skip
- Protection model: instruction redundancy
 - Formally verified countermeasure model [Moro et al., 2014]

- Platform
 - STM32 F100: ARM Cortex-M3
 - Frequency: 24 MHz
 - Instruction Set: Thumb2

Experimental results for AES

	Opt. level	Unprotected		Protected		Overhead		Moro et al [3]

T. Barry, D. Couroussé, and B. Robisson “Compilation of a Countermeasure Against Instruction-Skip Fault Attacks,” in Proceedings of the Third Workshop on Cryptography and Security in Computing Systems (CS2), 2016.

DYNAMIC PROTECTION: CODE POLYMORPHISM

POLYMORPHIC RUNTIME CODE GENERATION

Definition

- Regularly **changing the behavior** of a (secured) component, **at runtime**, while maintaining **unchanged its functional properties**, with runtime code generation

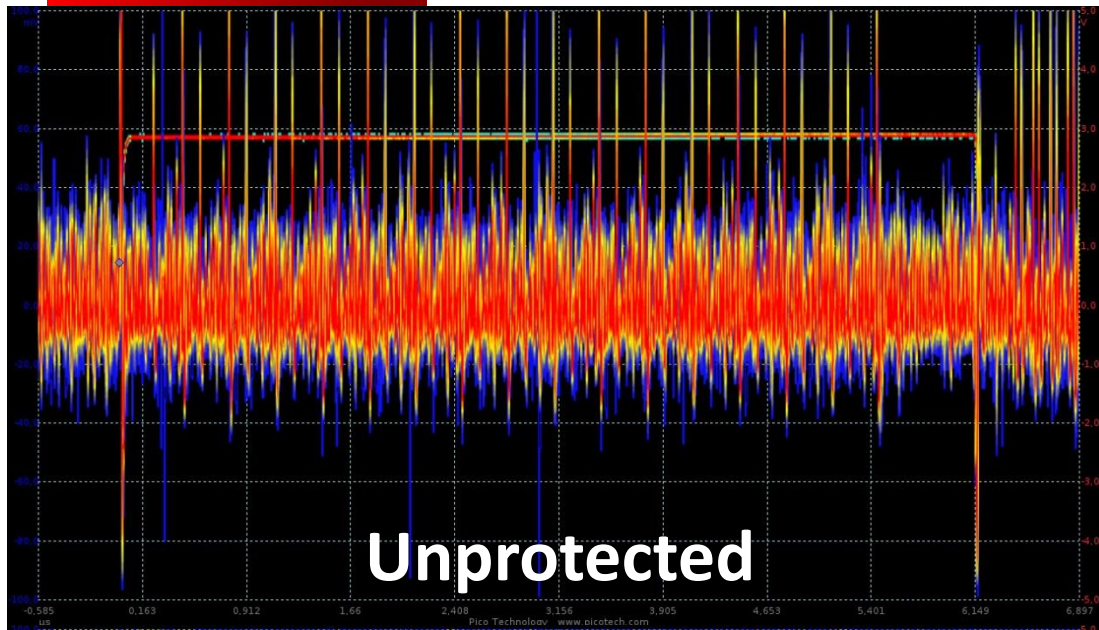

COGITO

POLYMORPHIC RUNTIME CODE GENERATION

Definition

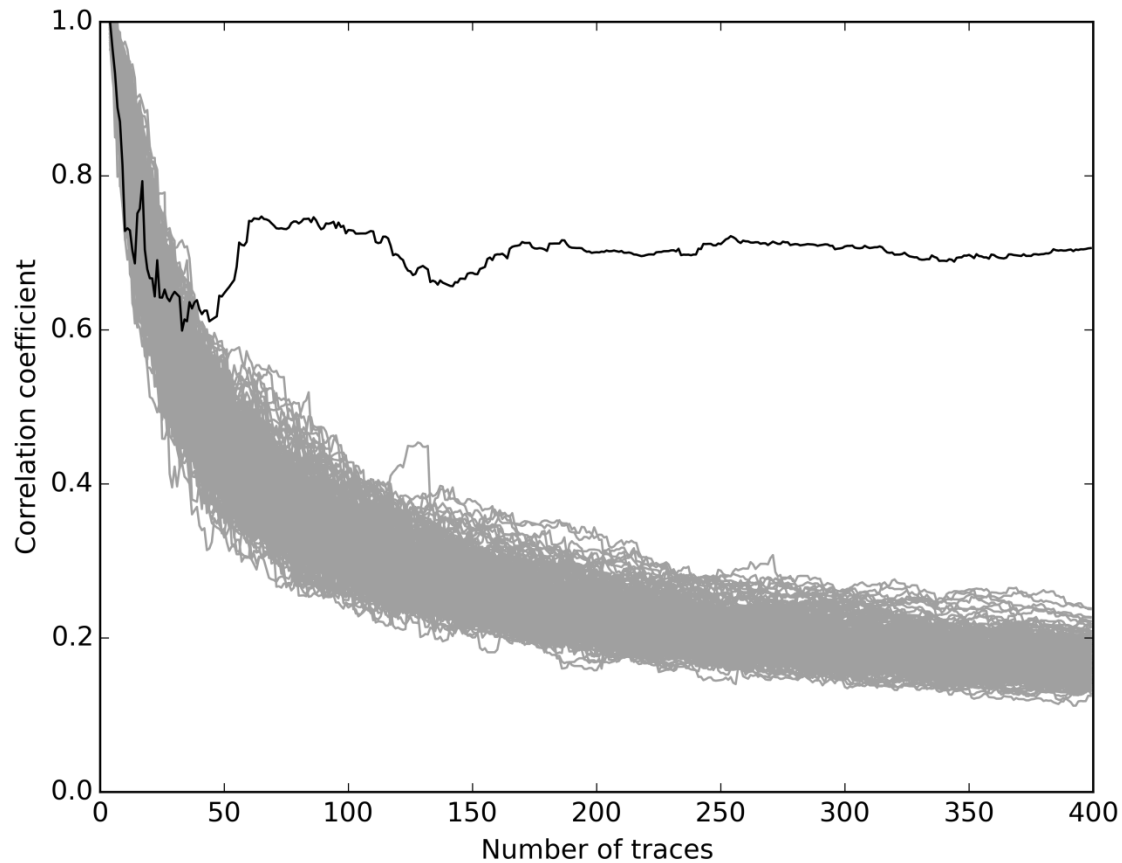

- Regularly **changing the behavior** of a (secured) component, **at runtime**, while maintaining **unchanged its functional properties**, with runtime code generation
- **Protection against physical attacks: side channel & fault attacks**
 - polymorphism changes the **spatial** and **temporal** properties of the secured code
 - Compatible with State-of-the-Art HW & SW Countermeasures
- **Protection against reverse engineering of SW**
 - the secured code is not available before runtime
 - the secured code regularly changes its form (code generation interval ω)
- **deGoal: runtime code generation for embedded systems**
 - fast code generation, tiny memory footprint

ILLUSTRATION

Reference version:
unprotected AES-8

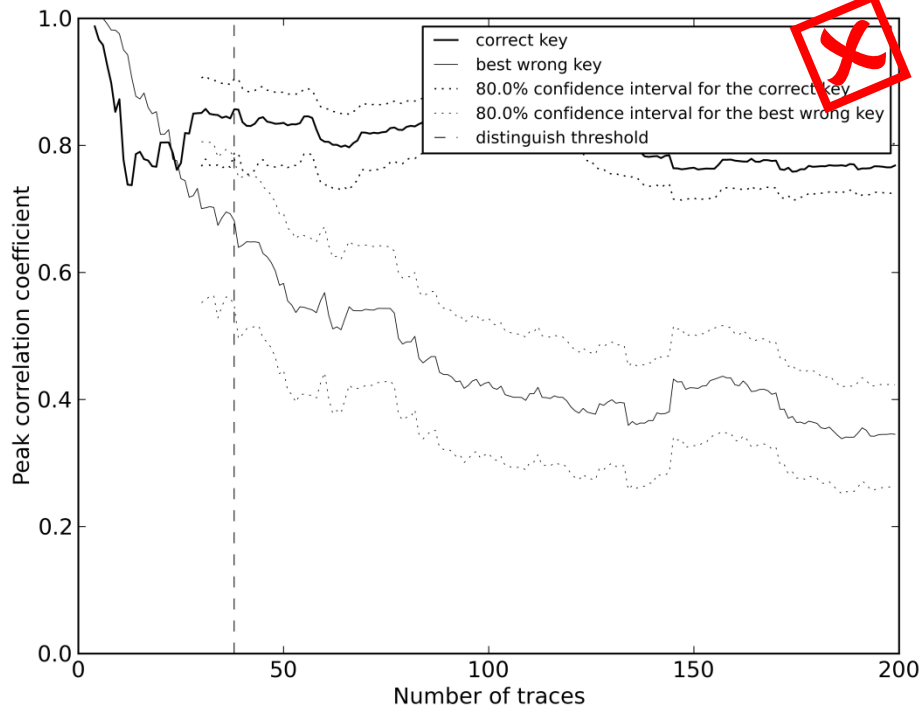

IMPACT OF POLYMORPHISM ON CPA

Effect of the code generation interval

Reference implementation

Polymorphic version,
code generation interval: 500

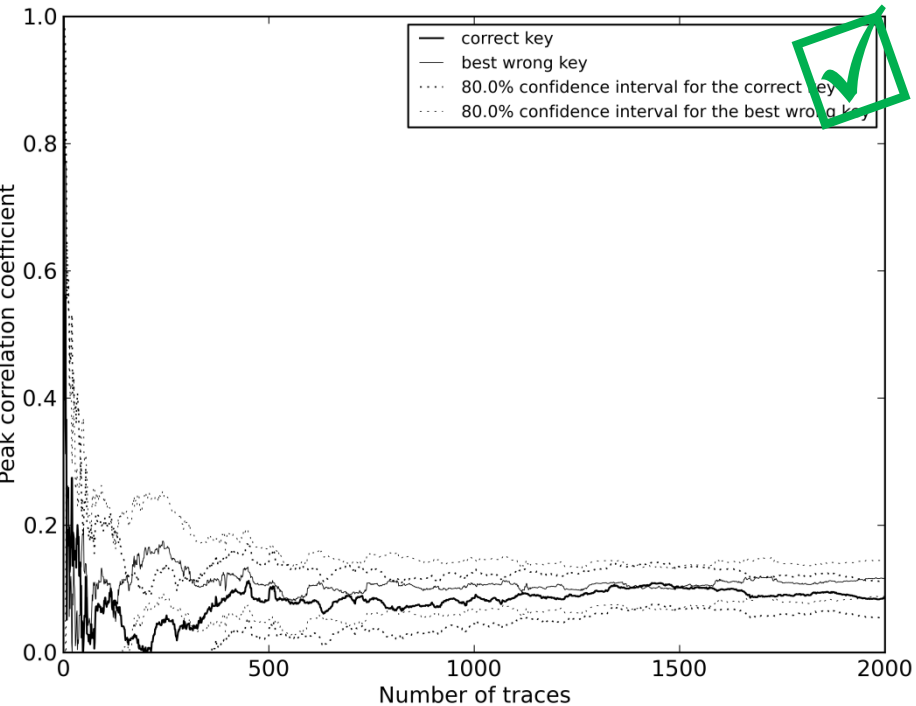

Distinguish threshold = 39 traces

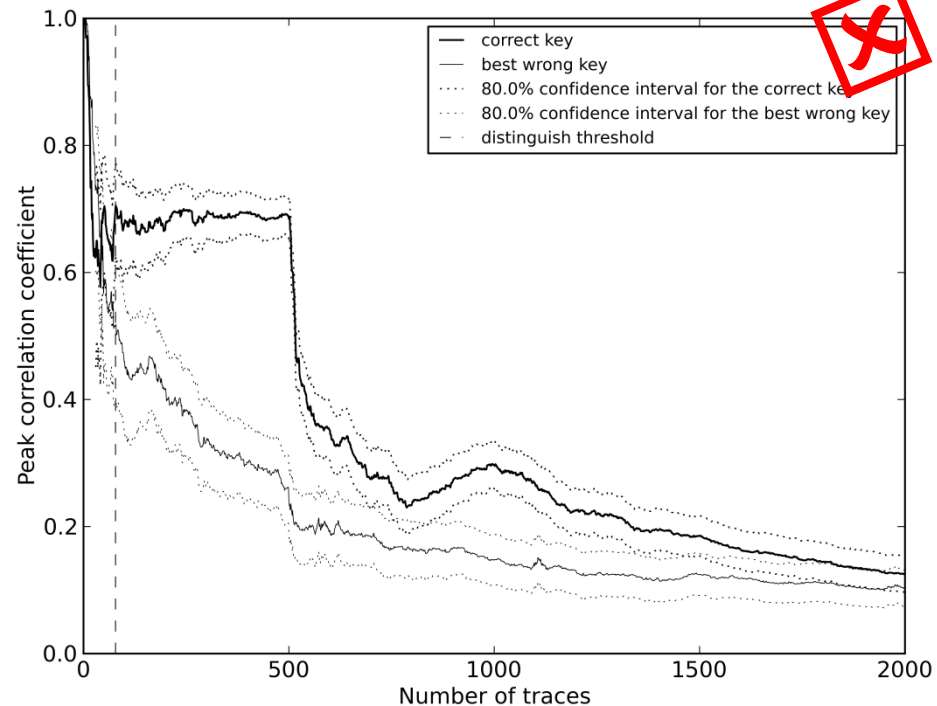

Distinguish threshold = 89 traces

Polymorphic version
code generation interval: **20**

Distinguish threshold > 10000 traces

Polymorphic version,
code generation interval: **500**

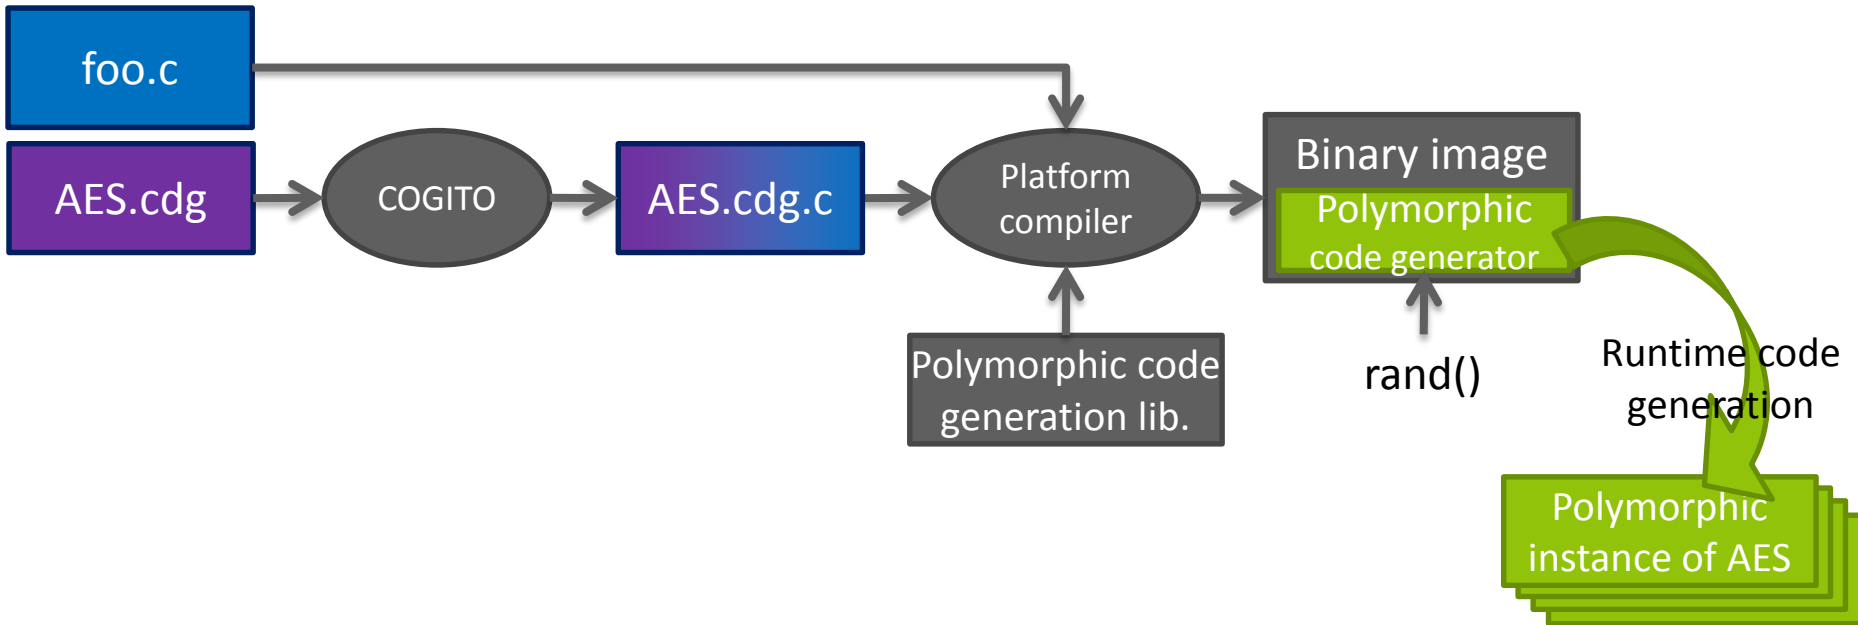

Distinguish threshold = 89 traces

            Free rstatei, rsboxi
        ]#
    }
}
```

Polymorphism is a *hiding* countermeasure

- The leakage instruction:
 - is not modified as compared to the same instruction in the reference version (for eval purposes)
- Unprotected AES: $N < 50$ traces \Rightarrow Polymorphic: $N > 1000000$ traces
 - But data leakage is still available in the traces

... compatible with masking
